Iron (Ī'ŭrn), *n.* [OE. *iren*, AS. *Īren, Īsen, Īsern*; akin to D. *ijzer*, OS. *īsarn*, OHG *īsarn, īsan*, G *eisen*, Icel. *īsarn, járn*, Sw. & Dan. *jern*, and perh. to E. *ice*; cf. Ir *iarann*, W. *haiarn*, Armor. *houarn*.] **1.** (*Chem.*) The most common and most useful metallic element, being of almost universal occurrence, usually in the form of an oxide (as *hematite, magnetite*, etc.), or a hydrous oxide (as *limonite, turgite*, etc.). It is reduced on an enormous scale in three principal forms; viz., *cast iron, steel*, and *wrought iron*. Iron usually appears dark brown, from oxidation or impurity, but when pure, or on a fresh surface, is a gray or white metal. It is easily oxidized (rusted) by moisture, and is attacked by many corrosive agents. Symbol Fe (Latin *Ferrum*). Atomic weight 55.9. Specific gravity, pure iron, 7.86; cast iron, 7.1. In magnetic properties, it is superior to all other substances.

☞ The value of iron is largely due to the facility with which it can be worked. Thus, when heated it is malleable and ductile, and can be easily welded and forged at a high temperature. As *cast iron*, it is easily fusible; as *steel*, is very tough, and (when tempered) very hard and elastic. Chemically, iron is grouped with cobalt and nickel. *Steel* is a variety of iron containing more carbon than wrought iron, but less than cast iron. It is made either from wrought iron, by roasting in a packing of carbon (*cementation*) or from cast iron, by burning off the impurities in a Bessemer converter (then called *Bessemer steel*), or directly from the iron ore (as in the Siemens rotatory and regenerating furnace).

2. An instrument or utensil made of iron; — chiefly in composition; as, a flat*iron*, a smoothing *iron*, etc.

See *Bog ore*, under BOG. — **Cast iron** (*Metal.*), an impure variety of iron, containing from three to six per cent of carbon, part of which is united with a part of the iron, as a carbide, and the rest is uncombined, as graphite. If there is little free carbon, the product is *white iron*; if much of the carbon has separated as graphite, it is called *gray iron*. See also CAST IRON, in the Vocabulary. — **Fire irons.** See under FIRE, *n.* — **Gray iron.** See *Cast iron* (above). — **In irons** (*Naut.*), said of a sailing vessel, when, in tacking, she comes up head to the wind and will not fill away on either tack. — **Magnetic iron.** See MAGNETITE. — **Malleable iron** (*Metal.*), iron sufficiently pure or soft to be capable of extension under the hammer, also, specif., a kind of iron produced by removing a portion of the carbon or other impurities from cast iron, rendering it less brittle, and to some extent malleable. — **Meteoric iron** (*Chem.*), iron forming a large, and often the chief, ingredient of meteorites. It invariably contains a small amount of nickel and cobalt. Cf. METEORITE. — **Pig iron**, the form in which cast iron is made at the blast furnace, being run into molds, called *pigs*. — **Reduced iron.** See under REDUCED. — **Specular iron.** See HEMATITE. — **Too many irons in the fire**, too many objects requiring the attention at once. — **White iron.** See *Cast iron* (above). — **Wrought iron** (*Metal.*), the purest form of iron commonly known in the arts, containing only about half of one per cent of carbon. It is made either directly from the ore, as in the Catalan forge or bloomery, or by purifying (*puddling*) cast iron in a reverberatory furnace or refinery. It is tough, malleable, and ductile. When formed into bars, it is called *bar iron*.

The Jesuit novice after two years becomes a Scholastic, and takes his first vows of poverty, chastity, and obedience simply. Some years after, at the close of a second novitiate, he takes his second vows and is ranked among the Coadjutors or Professed. The Professed are bound by a fourth vow, from which only the pope can dispense, requiring them to go wherever the pope may send them for missionary duty. The Coadjutors teach in the schools, and are employed in general missionary labors. The Society is governed by a General who holds office for life. He has associated with him "Assistants" (five at the present time), representing different provinces. The Society was first established in the United States in 1807 The Jesuits have displayed in their enterprises a high degree of zeal, learning, and skill, but, by their enemies, have been generally reputed to use art and intrigue in promoting or accomplishing their purposes, whence the words *Jesuit*, *Jesuitical*, and the like, have acquired an opprobrious sense.

Syn. — Equity; law, right; rectitude, honesty, integrity; uprightness; fairness; impartiality. — JUSTICE, EQUITY, LAW. *Justice* and *equity* are the same, but human laws, though designed to secure justice, are of necessity imperfect, and hence what is strictly *legal* is at times far from being *equitable* or *just*. Here a court of *equity* comes in to redress the grievances. The real conflict is against the *working* of the *law*, this a court of *equity* brings into accordance with the claims of *justice*. (2) *Distributive* justice, which gives every man his exact deserts (3) *General* justice, which carries out all the *ends* of law, though not in every case through the precise channels of commutative or distributive justice; as we see often done by a parent or a ruler in his dealings with those who are subject to his control

K.

K (kā), the eleventh letter of the English alphabet, is a nonvocal consonant. The form and sound of the letter K are from the Latin, which used the letter but little except in the early period of the language. It came into the Latin from the Greek, which received it from a Phœnician source, the ultimate origin probably being Egyptian. Etymologically K is most nearly related to *c*, *g*, *h* (which see).

In many words of one syllable *k* is used after *c*, as in *crack*, *check*, *deck*, being necessary to exhibit a correct pronunciation in the derivatives, *cracked*, *checked*, *decked*, *cracking*; since without it, *c*, before the vowels *e* and *i*, would be sounded like *s*. Formerly, *k* was added to *c* in certain words of Latin origin, as in *musick*, *publick*, *republick*; but now it is omitted.

See *Guide to Pronunciation*, §§ 240, 178, 179, 185.

The larynx is connected with the pharynx by an opening, the glottis, which, in mammals, is protected by a lidlike epiglottis.

☞ In the framework of the human larynx, the thyroid cartilage, attached to the hyoid bone, makes the protuberance on the front of the neck known as *Adam's apple*, and is articulated below to the ringlike cricoid cartilage. This is narrow in front and high behind, where, within the thyroid, it is surmounted by the two arytenoid cartilages, from which the vocal cords pass forward to be attached together to the front of the thyroid. See SYRINX.

They are often improperly called *rock moss* or *tree moss.*

Each lichen is composed of white filaments and green, or greenish, rounded cells, and it is argued that the two are of different nature, the one living at the expense of the other. ☞ The *common log* consists of the *log-chip*, or *log-ship*, often exclusively called the *log*, and the *log line*, the former being commonly a thin wooden quadrant of five or six inches' radius, loaded with lead on the arc to make it float with the point up. It is attached to the log line by cords from each corner This line is divided into equal spaces, called *knots*, each bearing the same proportion to a mile that half a minute does to an hour The line is wound on a reel which is so held as to let it run off freely When the log is thrown, the log-chip is kept by the water from being drawn forward, and the speed of the ship is shown by the number of knots run out in half a minute There are improved logs, consisting of a piece of mechanism which, being towed astern, shows the distance actually gone through by the ship, by means of the revolutions of a fly, which are registered on a dial plate

Log'a-rithm (lŏg'ă-rĭth'm; 277), *n.* [Gr. λόγος word, account, proportion + ἀριθμός number: cf. F. *logarithme.*] (*Math.*) One of a class of auxiliary numbers, devised by John Napier, of Merchiston, Scotland (1550–1617), to abridge arithmetical calculations, by the use of addition and subtraction in place of multiplication and division. The relation of *logarithms* to common numbers is that of numbers in an arithmetical series to corresponding numbers in a geometrical series, so that sums and differences of the former indicate respectively products and quotients of the latter; thus,

0	1	2	3	4	Indices or logarithms.
1	10	100	1,000	10,000	Numbers in geometrical progression.

Hence, the logarithm of any given number is the exponent of a power to which another given invariable number, called the *base*, must be raised in order to produce that given number. Thus, let 10 be the base, then 2 is the logarithm of 100, because $10^2 = 100$, and 3 is the logarithm of 1,000, because $10^3 = 1{,}000$.

Arithmetical complement of a logarithm, the difference between a logarithm and the number ten. — **Binary logarithms.** See under BINARY. — **Common logarithms**, *or* **Briggs's logarithms**, logarithms of which the base is 10; — so called from Henry *Briggs*, who invented them. — **Gauss's logarithms**, tables of logarithms constructed for facilitating the operation of finding the logarithm of the sum or difference of two quantities from the logarithms of the quantities, one entry of those tables and two additions or subtractions answering the purpose of three entries of the common tables and one addition or subtraction. They were suggested by the celebrated German mathematician Karl Friedrich *Gauss* (died in 1855), and are of great service in many astronomical computations. — **Hyperbolic**, *or* **Napierian, logarithms**, those logarithms of which the base is 2 7182818; — so called from *Napier*, the inventor of logarithms — **Logistic**, *or* **Proportional, logarithms.** See under LOGISTIC

☞ In all air-breathing vertebrates the lungs are developed from the ventral wall of the esophagus as a pouch which divides into two sacs. In amphibians and many reptiles the lungs retain very nearly this primitive saclike character, but in the higher forms the connection with the esophagus becomes elongated into the windpipe and the inner walls of the sacs become more and more divided, until, in the mammals, the air spaces become minutely divided into tubes ending in small air cells, in the walls of which the blood circulates in a fine network of capillaries. In mammals the lungs are more or less divided into lobes, and each lung occupies a separate cavity in the thorax See RESPIRATION
